In November 2021, black mildew was observed on leaves of *Duranta erecta* L. (Verbenaceae) in the Campus of Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista, Bahia, Brazil. Previous analyzes of the fungal structures revealed that they belonged to a Meliolaceae fungus. The identification of the fungus was carried out through morphological characterization, and comparison with other Meliolaceae species described in the literature. Based on these morphological characteristics, the pathogen was identified as *Asteridiella pittieri*.

Key words: Biotrophic fungus, black mildew, golden dew drop.

Morfologia e histologia de *Asteridiella pittieri* (Meliolales, Ascomycota) em *Duranta erecta* L. Em novembro de 2021 foram observadas colônias negras de um fungo em folhas de *Duranta erecta* L. (Verbenaceae), no campus da Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista, Bahia. Análises prévias das estruturas fúngicas demonstraram ser um fungo pertencente à família Meliolaceae. A identificação da espécie foi realizada por meio de caracterização morfológica e comparação com outras espécies descritas de Meliolaceae. Baseado em semelhanças morfológicas esse fungo parasita foi identificado como *Asteridiella pittieri*.

Palavras-chave: Fungo biotrófico, míldio negro, pingo de ouro.

Duranta erecta L. is a species of the Verbenaceae family. It is a plant native to the Americas, widely distributed in the Florida Peninsula, Central America, Caribe, and South America. It has a shrub-tree habit, rarely a climber, with lilac flowers and yellow-orange drupaceous fruits (WFO 2023). It is popularly known as “pingo-de-ouro”, “rocío de oro”, “garbancillo”, and “golden dew drop”. This plant is widely cultivated in Brazil, especially in Bahia, Sergipe, Mato Grosso, Espírito Santo, Minas Gerais, Rio de Janeiro, São Paulo, Paraná, Rio Grande do Sul, and Santa Catarina (Moroni, 2023). It is considered invasive in several countries (Moroni et al., 2018).

Due to its traditional ornamental status, the occurrence of leaf spots or fungal colonies on these plants compromises the decorative function of the species.

In November 2021, a black mildew was observed occurring on leaves of *Duranta erecta* (Figure 1a-b) in the campus of Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista, Bahia. Previous analyzes of the fungal structures revealed that they belonged to a Meliolaceae fungus. Fungi in this taxonomic group are biotrophic parasites of plants, causing minimal damage to the host plants (Hongsanan et al., 2015).

This study aimed to identify the black mildew found on the host species *Duranta erecta*. Specimens were deposited in the HUESBVC Herbarium and registered under the reference HUESBV 10097. The plant species was determined according to Moroni & O’Leary (2020) and taxonomic classification following Angiosperm Phylogeny Group (2016).

Fungal identification was conducted morphologically and comparison with described Meliolaceae species (Hansford, 1961; Pereira et al., 2006.). Thirty measurements were taken for each structure under an optical microscope. The measurement results were presented in the format: (minimum) (average - standard deviation) - (average + standard deviation) (maximum).

Fresh anatomical sections of leaves infected with the fungus were also made. The slides were prepared with distilled water and cotton blue stain and photographed under a Leica DM750 microscope equipped with Leica ICC50HD digital camera and Leica LAS EZ software. Scale bars were calculated as described in Leitão (2016).

The host species is *D. erecta* - synonym *D. repens* L. (Moroni 2023, WFO 2023).

Description

Asteridiella pittieri (Toro) Hansf., Beih. Sydowia 2: 685 (1961).

The fungus generally establishes itself on the upper surface of petioles and leaves, with dark brown septate hyphae, thick-walled, measuring 7.5 to 9 µm in diameter. The hyphae produce fine hyphal pegs that penetrate the outer periclinal wall of leaf epidermal cells, where they form coraloid appressoria (Figure 2e-g). Bicellular, alternating, dark brown hyphopodia, straight to slightly curved, measuring (17) 18-20.5 (20) × (10) 11-13.8 (15) µm (Figure 1c and 2d). Phialides, opposite or alternating, mixed with hyphopodia, measuring (17) 18.5-23.5 (25) × (7) 7.8-9.5 (10) µm. Perithecia scattered, black, globose, with crenulate surface, (150) 175-230 (232) µm in diameter (Figure 1d-e). Ascii unitunicate, elliptical, thin-walled, with two ascospores per ascus (Figure 2a). Ascospores dark brown, narrowly elliptical, obtuse, 4-septate (rarely with 2-3 septate), constricted, measuring (39) 39.5-42.5 (44) × (14) 14.6 × 16.0 (18) µm (Figure 2b-c).

Examined specimens

BAHIA: Vitória da Conquista, Campus da Universidade Estadual do Sudoeste da Bahia (), em folhas de *Duranta repens* 10/02/2023, N.L.S. Mesquita and A. Santos, HUESBV 10097.

Comments

The species was identified based on morphology and measurements of the fungus in comparison with the description of Hansford (1961). The fungus has been reported in Brazil on *D. erecta* in the states of Minas Gerais and São Paulo (Pereira et al., 2006), in Colombia, Mexico, and Venezuela (Hansford, 1961), and also reported for *D. mutisii* L.F. in Venezuela (GBIF, 2023).
